Astronomical Challenge

Astronomical Challenge

Classifying celestial objects into stars, galaxies or quasars.

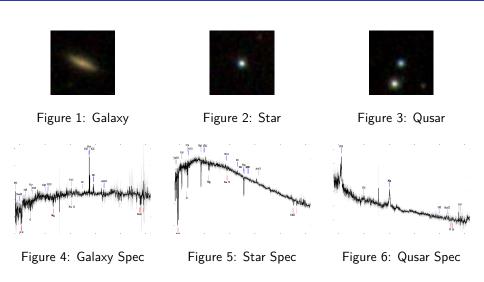

- Stars: a luminous sphere of plasma held together by its own gravity.
- Galaxy: a massive, gravitationally bound system that consists of stars, stellar remnants, interstellar gas, dust, and dark matter.
- Quasars: a very energetic and distant active galactic nucleus, with its energy output sometimes surpassing that of the rest of the galaxy combined.

Idea

- There are a lot of classification models: KNN, Tree, Logistic Regression, Neural Networks
- Different models may perform differently on same data
- Can we combine them together to make more accurate classification?
- Voting Classifier

Data & Preprocessing

Images

Metadata

Table 1: Metadata of the celestial objects

vars	explanations			
ra	Right Ascension angle (at J2000 epoch)			
dec	Declination angle (at J2000 epoch)			
u	Ultraviolet filter			
g	Green filter			
r	Red filter			
i	Near Infrared filter			
z	Infrared filter			
run	Run Number			
rerun	Rerun Number			
camcol	Camera column			
field	Field number			
specobjid	Unique ID used for optical spectroscopic objects			
class	Object class			
redshift	Redshift value based on the increase in wavelength			
plate	Plate			
mjd	Modified Julian Date			

EDA

- Missing Values:
 - Metadata: 3, Regression Imputation
 - Image of Spectra: 14115
- Samples for each category: 33333
- Correlationship

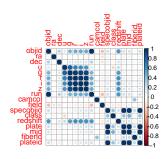

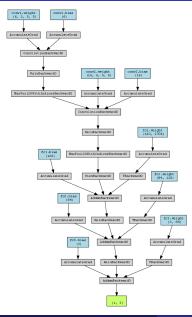

Figure 7: Correlationship of Variables

Methodology

Meta Data

- Explanatory Variables: u, g, r, i, z, redshift
- Response Variable: class
 - GALAXY: 0
 - QSO: 1
 - STAR: 2
- **kNN**: k = 3
- Decision Tree:
 - Gini impurity
 - max depth: 4
- Logistic Regression
 - C: 1
 - penalty: 12
 - $P(Y_i = k) = \frac{e^{\beta_k \cdot X_i}}{\sum_{j=1}^3 e^{\beta_j \cdot X_i}}, i = 0, 1, 2$

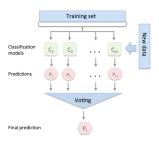

Images

- Structure:
 - 2 layers of convolution and 1 maxpooling
 - 3 layers of full connecting
- Output:
 - $\vec{y} = (y_1, y_2, y_3)$
 - $y_{pred} = argmax_i\{\vec{y}\}$
 - Probability through softmax $P(y = j \mid \mathbf{z}) = \frac{e^{z_j}}{\sum_{i=1}^{3} e^{z_k}}$
- Training:

SGD with different momentum, Adam, 10 epoch, batch size 64,Ir 0.001

Voting Classifier

- Soft Voting:
 - Models $\{C_1, \dots C_n\}$
 - For a given inputs, C_i has a predict probability $P_i(y_i|x)$
 - The probabilities for voting classifier $P(y_j|x) = \frac{1}{m} \sum_{i=1}^{m} P_i(y_j|x)$
 - The prediction $p(x) = \arg \max_{y_j} P(y_j|x)$
- Weighted Hard Voting: For a given inputs, C_i has a predict $y^i|x:y^i_{k=j}=1, y^i_{k\neq j}=0$ $y_{pred}=\sum_i w_i\cdot y^i|x$, here we use accuracy of each model as their weight, the predict class is $argmax_i$ y_{pred}
- Construction:

The candidate models are KNN, Logistic Regression, Decision Tree, CNN for celestial objects image and CNN for spectrum image.

Results

Metadata

Decision Tree:

• Logistic Regression:

Table 2: Coefficients of Logistic Regression

	Intercept	u	g	r	i	z	redshift
Galaxy	15.09801	1.110865	-1.698055	-0.1525521	0.6145228	-0.0238246	23.35724
Qso	16.80773	-2.883481	5.212935	0.7959545	-1.2216091	-2.1410609	32.50714
Star	-31.90574	1.772616	-3.514880	-0.6434025	0.6070863	2.1648855	-55.86438

Metadata

• The accuracy of KNN: 96.80

• Soft voting: 97.75

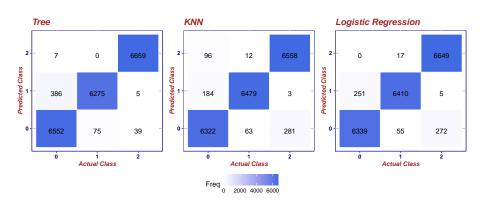

Figure 8: Confusion Matrices of Metadata Models

Images

- The accuracy of CNN of images 91.73
- Soft voting: 97.71

F1	Galaxy	0.953	0.9628	0.9564	0.9628	0.8969	0.9851	0.98
	Qso	0.9802	0.9642	0.9751	0.8759	0.9164	0.9865	0.9833
	Star	0.971	0.9962	0.9784	0.9109	0.861	0.9976	0.9956

Note:

M: Metadata. IC: Image of Celestial Objects. IS: Image of Spectrum.

Conclusions

Conclusions

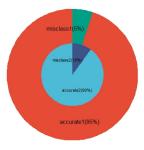

Figure 11: Voting

- For all the combination of classifiers, Soft Voting performs better than Hard Voting
- For every data set, Voting method performs equal or better than single model

Future Work

Future Work

- Include more models
- Use less data
- Add noise to the data
- Consider more voting methods
